

said driving tube such that the key driving tube is rotated because of the rotation of said driving tube.

In the Abstract

Please amend the Abstract as follows:

A lock engaging-and-disengaging mechanism, having: a driving tube, containing at least one hole on the inner wall of the tube, and a key driven tube, flexibly installed to the inner tube portion of the first end of the driving tube, and containing at least one hole on the wall of the tube; a sideways component, being installed in the hole on the key driven tube, and allowing the options of locking **engaging** or ~~not locking~~ **disengaging** with the hole on the driving tube, an axially sliding component[[,]] being inserted inside the key driven tube[[,]] ~~which containing~~ **and having** a non-axial slot, a rotatable component[[,]] ~~being is~~ inserted inside the axially sliding component, ~~which~~ **the rotatable component** containing a pin dipping into the non-axial slot of ~~the~~ axially sliding component[[,]] ~~by means of the rotational action~~ **on rotation** of the rotatable component, enabling ~~coactions~~ **movement** of the pin of ~~the~~ axially sliding component and the non-axial slot of ~~the~~ axially sliding component[[,]] so as to make ~~the~~ axially sliding component generate axial displacement[[,]] in order to control the movement of the sideways component that is installed on the key driven tube.
